

## Diversity maintenance in particle filters

Gert Kootstra

# Overview

---

- ▶ Particle filters for localization
- ▶ Similarities between particle filters and genetic algorithms
- ▶ Problem of premature convergence
- ▶ Niching methods
- ▶ Experiments
- ▶ Results
- ▶ Conclusion

# Particle filters

---

- ▶ A particle filter represents the probability distribution with a set of particles

- ▶ Distribution can take any form
- ▶ Density of particle should approximate the true distribution. True for  $N \uparrow \infty$

# Monte-Carlo localization

---

- ▶ In MCL, a particle filter is used to estimate the position of the robot.
- ▶ Information used
  - ▶ Map of the environment
  - ▶ Sensory reading of the robot
  - ▶ Action (motion) performed by the robot

# Monte-Carlo localization

---

- ▶ **Set of particles**  $S_t = \{(x_t^i, w_t^i) \mid i = 1, \dots, N\}$ 
  - ▶ Each particle is a hypothesis about the location  $x_t^i$
  - ▶  $w_t^i$  is the weight (probability) of that particle
- ▶ **Start with random distribution of particles**
- ▶ **Iterative optimization process**
  1. Apply motion model  $x_{t+1}^i = f(x_t^i, u_t^i)$
  2. Apply sensor model  $w_{t+1}^i = g(x_{t+1}^i, z_t^i)$
  3. Resample the particles

# Monte-Carlo localization

---

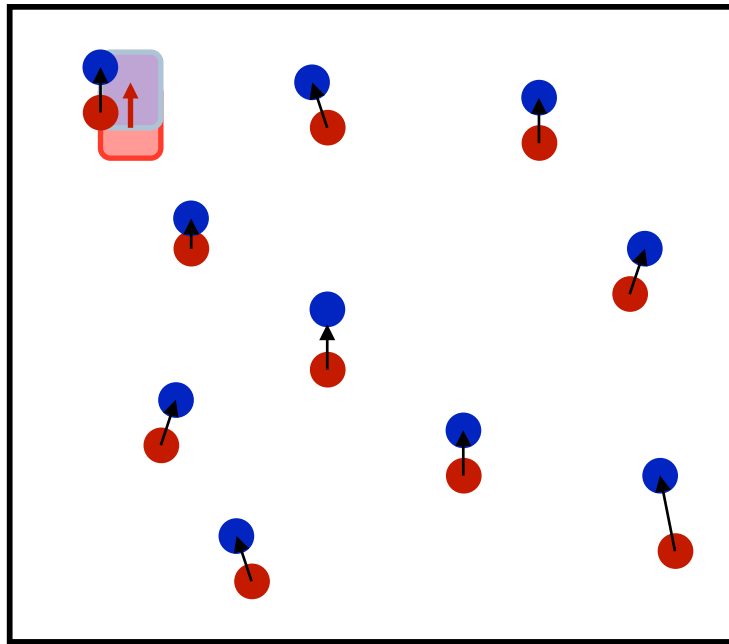

- ▶ Initial distribution: random

# Monte-Carlo localization

---

- ▶ **Applying motion model**
  - ▶ Next position of p's based on motion
  - ▶ Including noise to represent uncertainty

# Monte-Carlo localization

- ▶ Applying sensor model
  - ▶ Calculating the particle weights

Perception of robot,  $z$

'Perception' of particle  $z_t$

Calculate the weight  $P(z|x_3)$  using

# Monte-Carlo localization

---

- ▶ Resampling the particle population
  - ▶ Weight-proportional sampling

# Monte-Carlo localization

---

- ▶ Final distribution

# Problem: premature convergence

---

# Premature convergence

---

- ▶ Loss of diversity
- ▶ Makes the filter end up in a sub-optimal solution
- ▶ Especially when observations lead to ambiguous situations
  - ▶ In symmetrical environments (many office buildings)
  - ▶ With multiple solutions
  - ▶ With noisy sensors

# Random drift

---

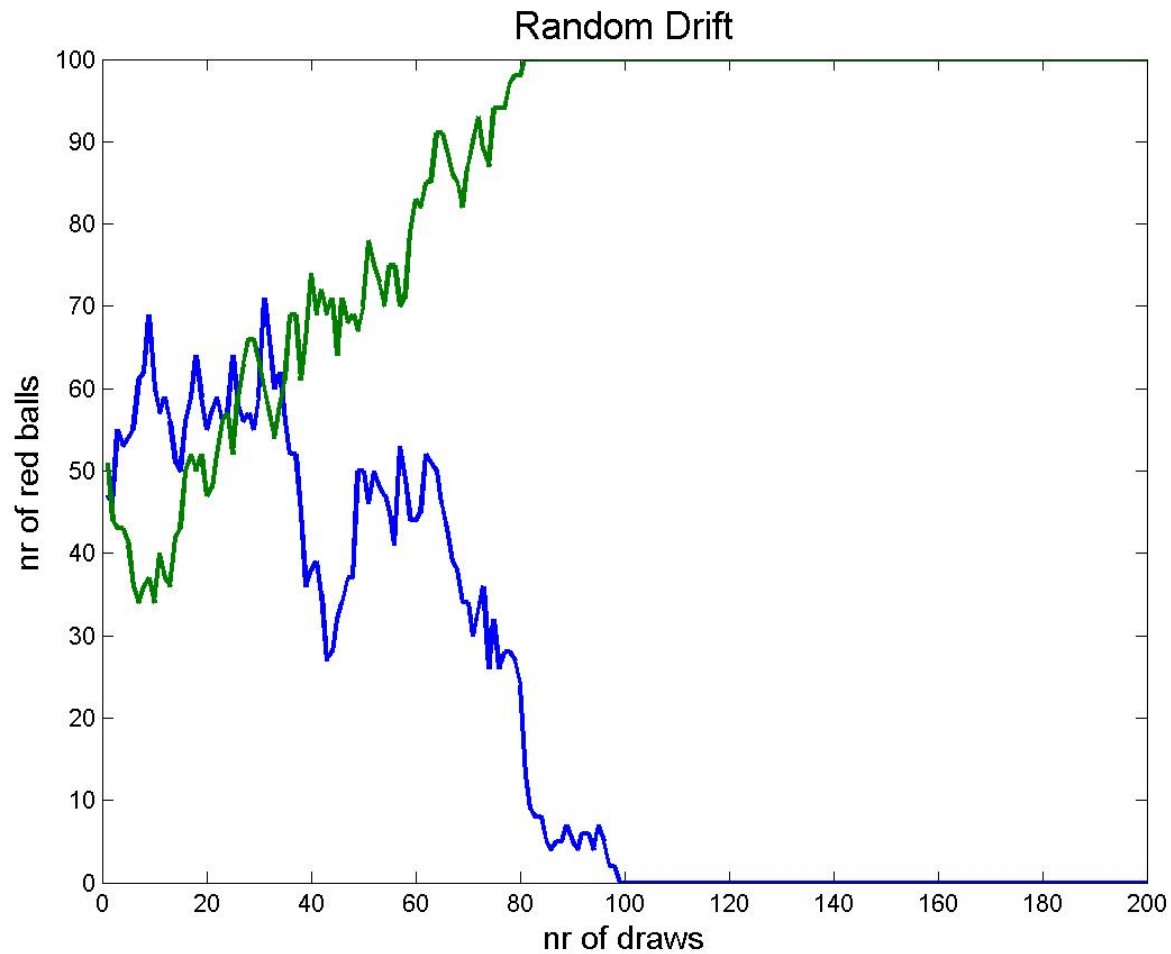

- ▶ Reason: random (genetic) drift
  - ▶ Consider 5 particles for solution A en 5 for B
  - ▶ All the same weight
  - ▶ This is what happens in the resampling process

# Random drift

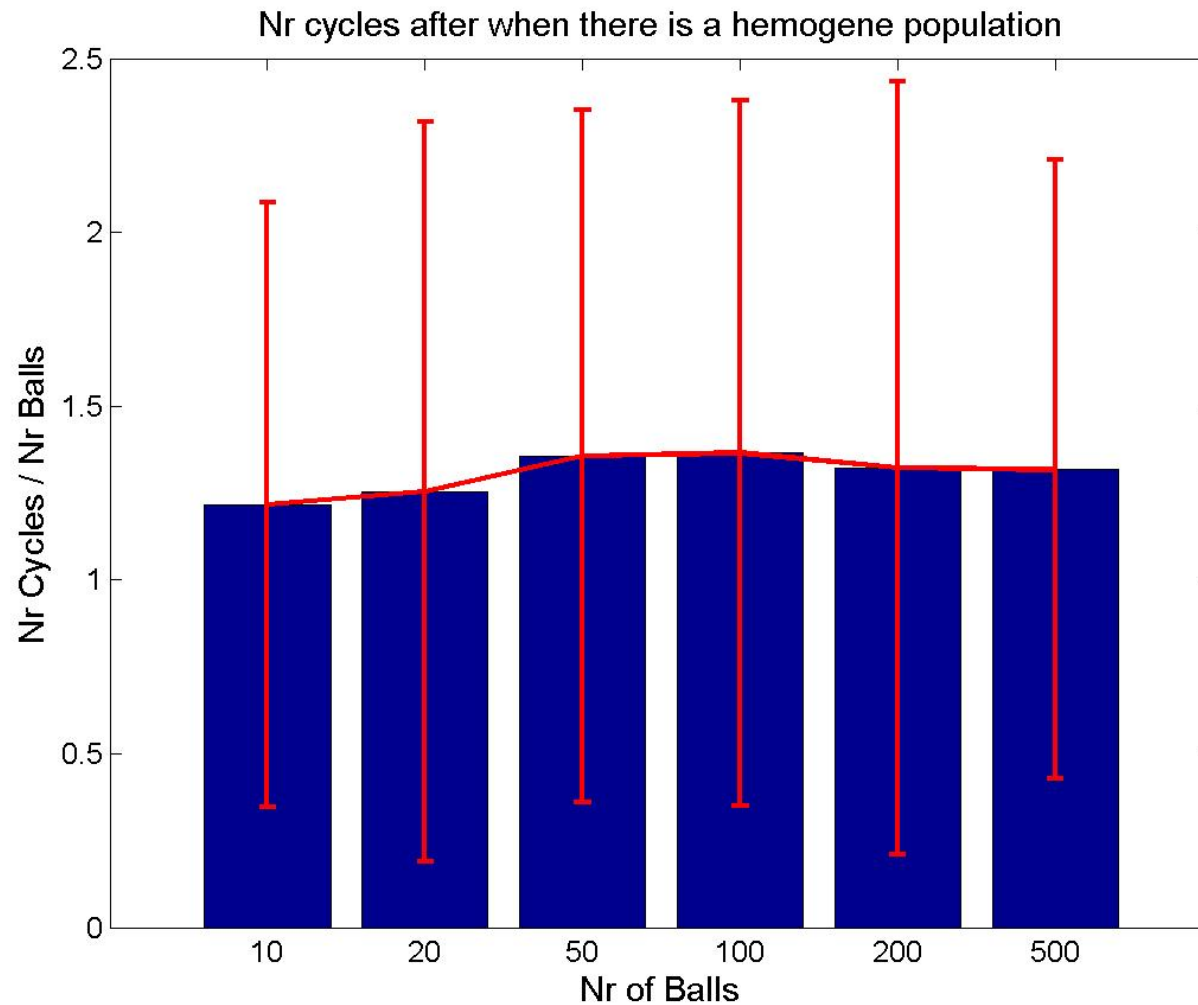

---

- ▶ Two examples with 100 particles starting 50-50

# Random drift

- ▶ Many examples: time to convergence

# Premature convergence

---

- ▶ Reason for this drift
  - ▶ The variance in the sampling method
  - ▶ Population after sampling might not resemble the weight distribution
  - ▶ Particles in different regions compete for limited resources ( $N$  particles in next generation)
- ▶ Variance of roulette-wheel sampling is particular high

# Stochastic universal sampling

---

- ▶ Stochastic universal sampling: lower variance

- ▶ Only one random number generator
  - ▶ Less variance in sampling:  $\pm 1$  particle
  - ▶ Also faster
  - ▶ However, premature convergence remains
    - ▶ Demo
- 

# Particle filters vs genetic algorithms

---

- ▶ Same mechanism: iterative optimization

Particle Filter	Genetic Algorithm
Particles	Individuals
Random initial distribution	Random initial distribution
Motion model + noise	Mutation (noise)
Transition model	Fitness function
Resampling	Reproduction (weight based)
Random drift	Genetic drift

- ▶ Same problems and same solutions

---

# Diversity in natural systems

---

- ▶ What is the reason that in nature there are many different species and not one due to genetic drift?
- ▶ Two of the answers:
  1. No competition between different niches
  2. Fitness advantage for species with less members (frequency-dependent selection)
- ▶ Niche
  - ▶ Environment for particular species (food, temp,...)

# 1. No competition between niches

---

- ▶ **Source of genetic drift**
  - ▶ competition between different niches for limited resources
- ▶ **But many species do not compete because of different niches**
  - ▶ No competition for space, food, etc.

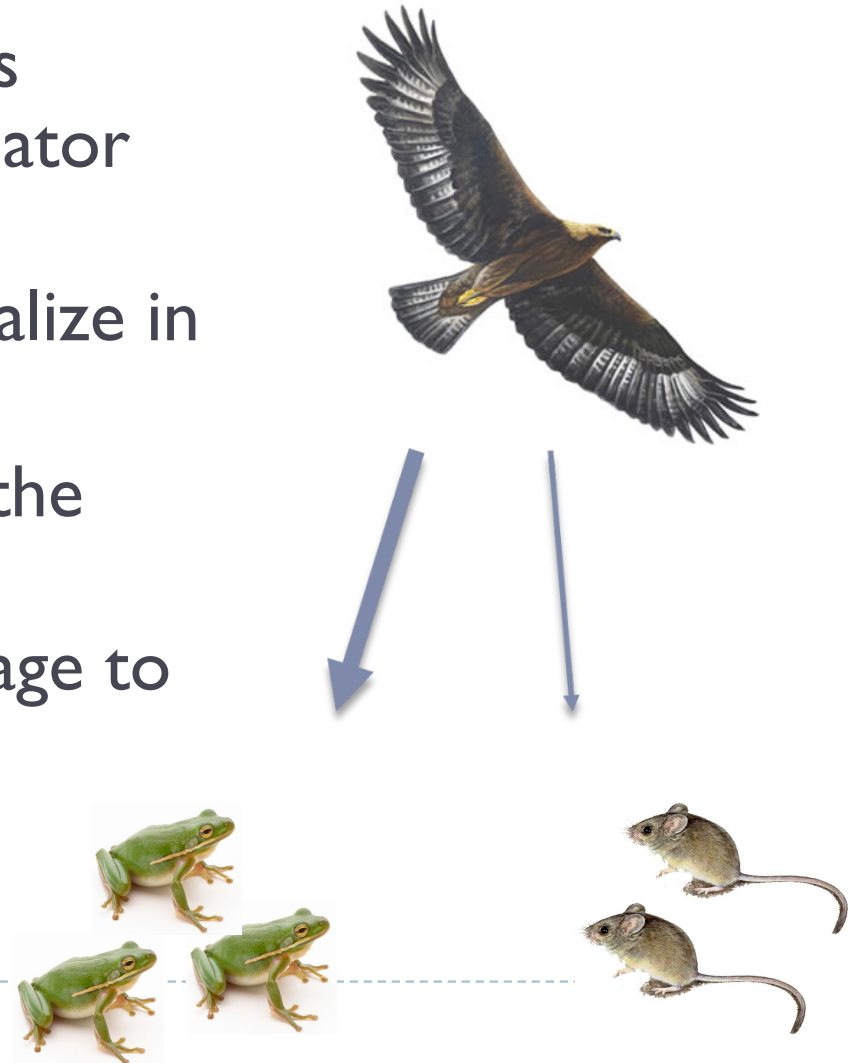

## 2. Frequency-dependent selection

---

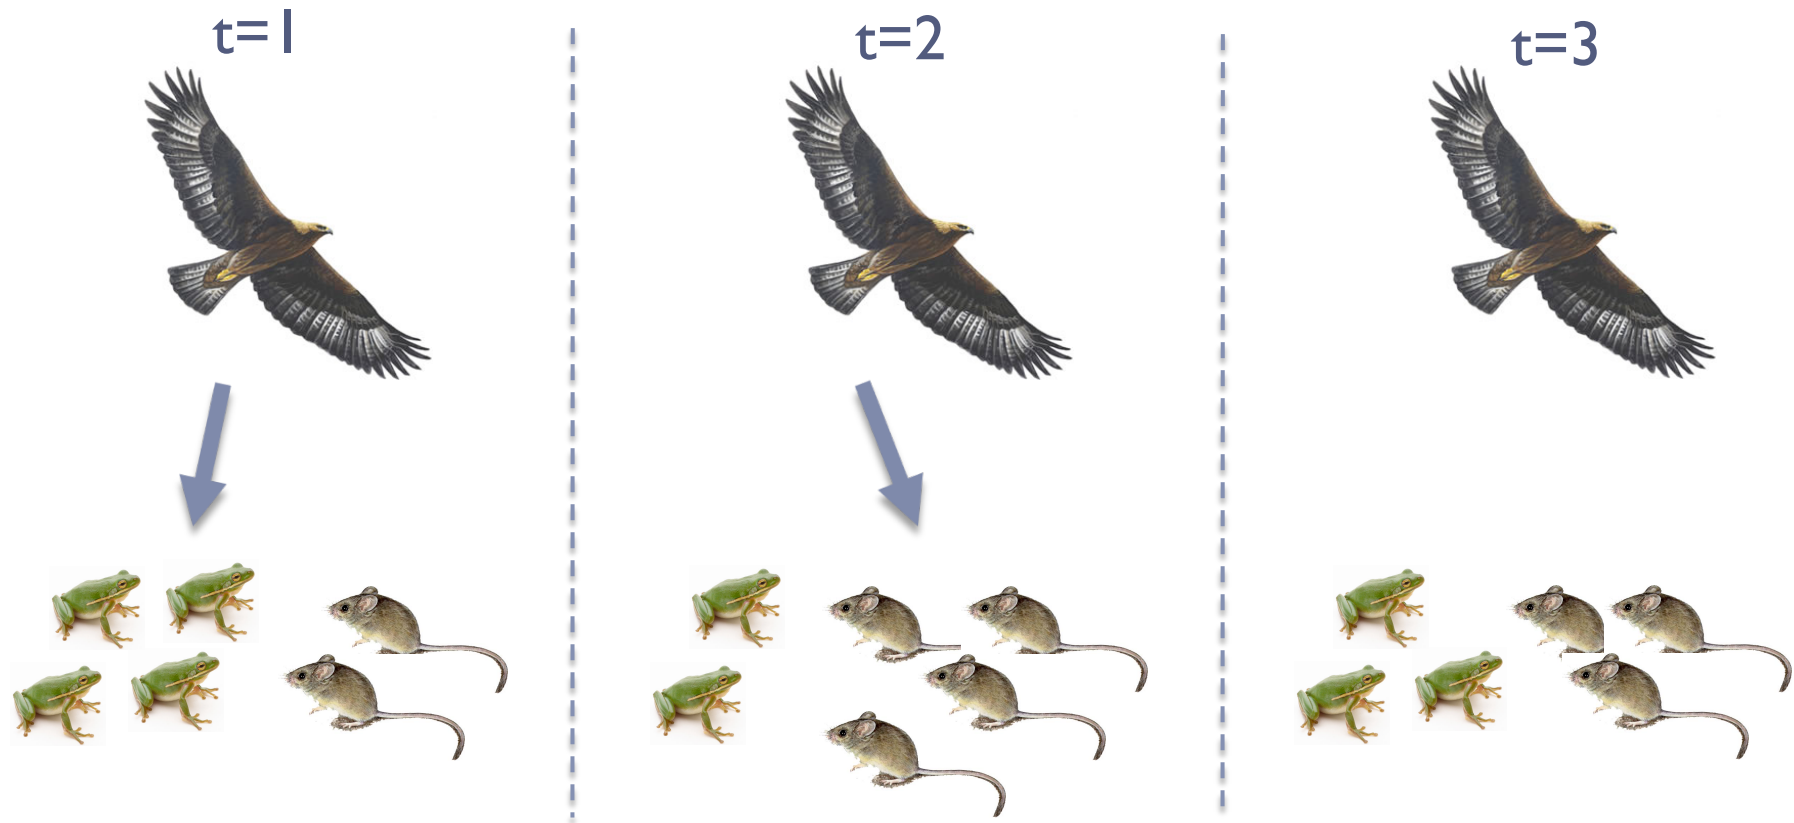

### ▶ Predator-prey systems

- ▶ Consider two prey species (mice, frogs) and one predator (eagle)
- ▶ The predator has to specialize in one of the two
- ▶ It obviously specializes in the largest group
- ▶ This gives a fitness advantage to the smaller group and disadvantage to the bigger

## 2. Frequency-dependent selection

---

- ▶ Smaller groups have advantage
  - ▶ Results in balance between group size
- 

# Niching methods in GA

---

## ▶ Terminology

- ▶ Niche                                  Solution
- ▶ Limit resource                      Limit nr of individuals

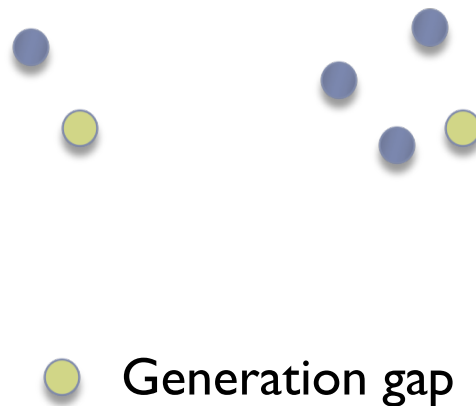

## ▶ Solutions in GA field: Niching methods

- ▶ Crowding
  - ▶ Sharing / Frequency dependent selection
  - ▶ Local selection
- 
- ▶

# Crowding / Closest of the Worst

---

- ▶ Apply motion and sensor model to all particles
- ▶ Crowding instead of the standard resampling:
  - ▶ Select part (20%) of the population, the **generation gap**, to reproduce using weight-proportional selection, so selecting the more probably particles

# Crowding / Closest of the Worst

---

- ▶ For every particle  $i$  in the generation gap
  - ▶ A proportion (1%), the **crowding factor**, is randomly sampled from the worst particles
  - ▶ The **nearest** particle in the crowding factor is replaced by particle  $i$ .

- ▶ Large groups: competition within the niche
  - ▶ Small groups: change to get a particle from another group
- 

# Frequency dependent selection

---

- ▶ Apply motion and sensor model to all particles
- ▶ Adjust the weights

- ▶ 
$$\hat{w}_{t+1}^i = w_{t+1}^i \cdot \sum_{j=1}^{2 \cdot N} \text{dist}(x_{t+1}^i, \text{rand\_particle})$$

- ▶ Fitness advantage for small groups

- ▶ Resample normally
- 

# Local selection

---

- ▶ Different method
- ▶ The size of the particle population adapts to the **carrying capacity** of the environment.
  - ▶ No competition for limited resources
  - ▶ A niche will maintain as many particles as suited for the niche's 'fitness'.
- ▶ Every particle now has an amount of energy

# Local selection

---

- ▶ Apply motion and sensor model to all particles
  - ▶ Divide world in bins and count particles per bin
  - ▶ For all particles
    - ▶ Update energy of the particle:  $E_{in}^i = w_{t+1}^i / \text{wbin}[x_{t+1}^i]$
    - ▶ *Reproduction or death* based on the amount of energy  $E_{t+1}^i = E_t^i + (E_{in} - E_{out})$ 
      - ▶  $E_{t+1}^i > \theta$  Make copy of particle and share energy
      - ▶  $E_{t+1}^i < 0$  Take particle out of the population
  - ▶ Stable niche size when  $E_{in} = E_{out}$
- 

# Experiments

---

- ▶ Test the algorithms in a highly symmetrical environment

- ▶ Particle filter needs to maintain all four possible solutions ●

- ▶ Subpopulations should be compact

- ▶ Estimation error should be small

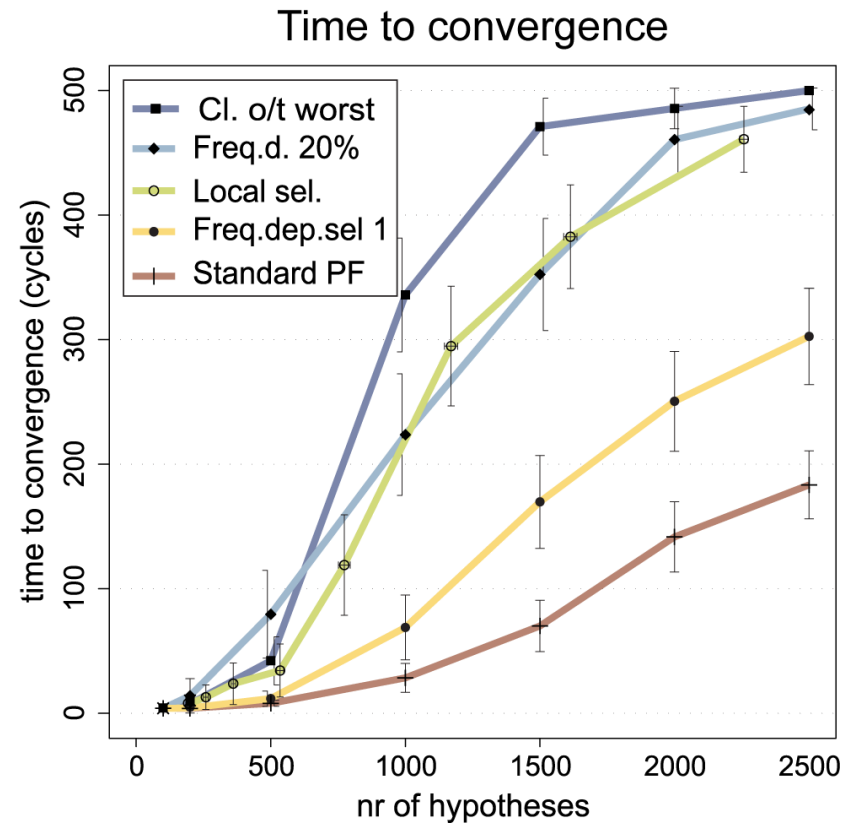

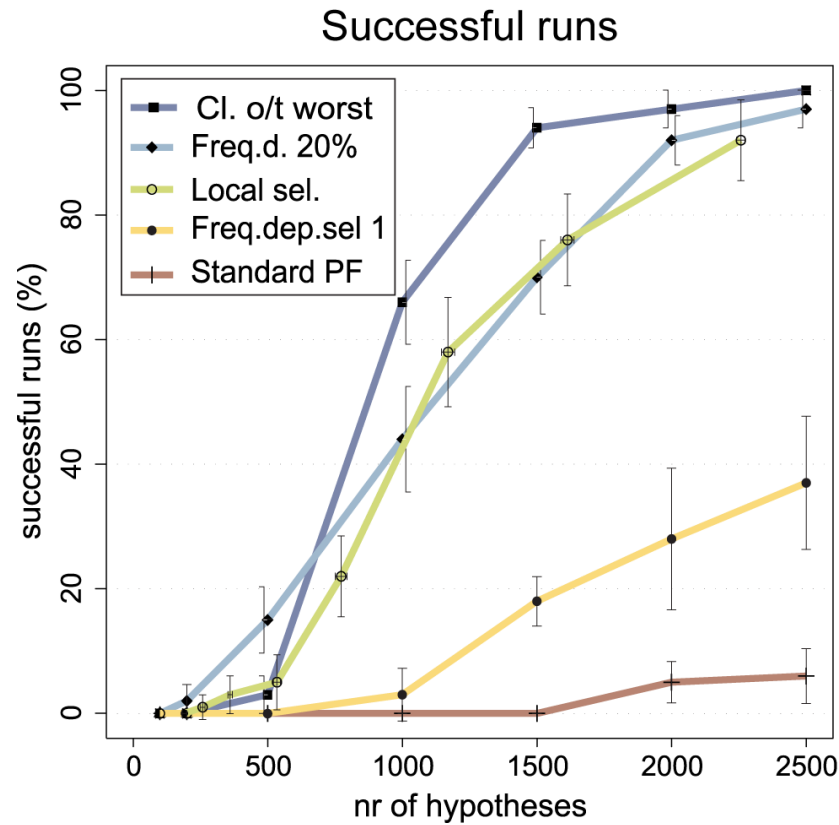

- ▶ Demonstration

---

# Results: Diversity maintenance

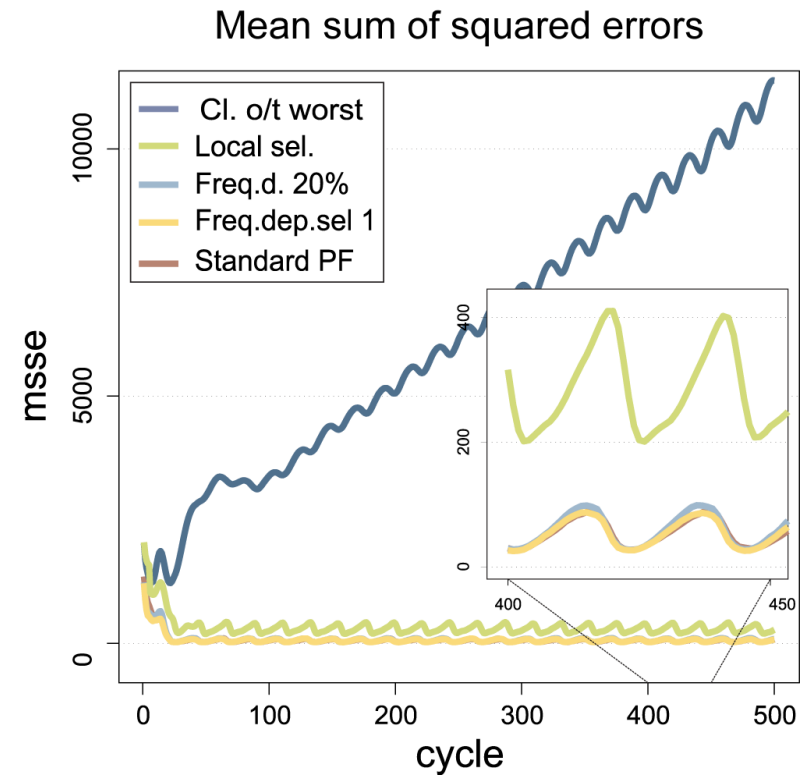

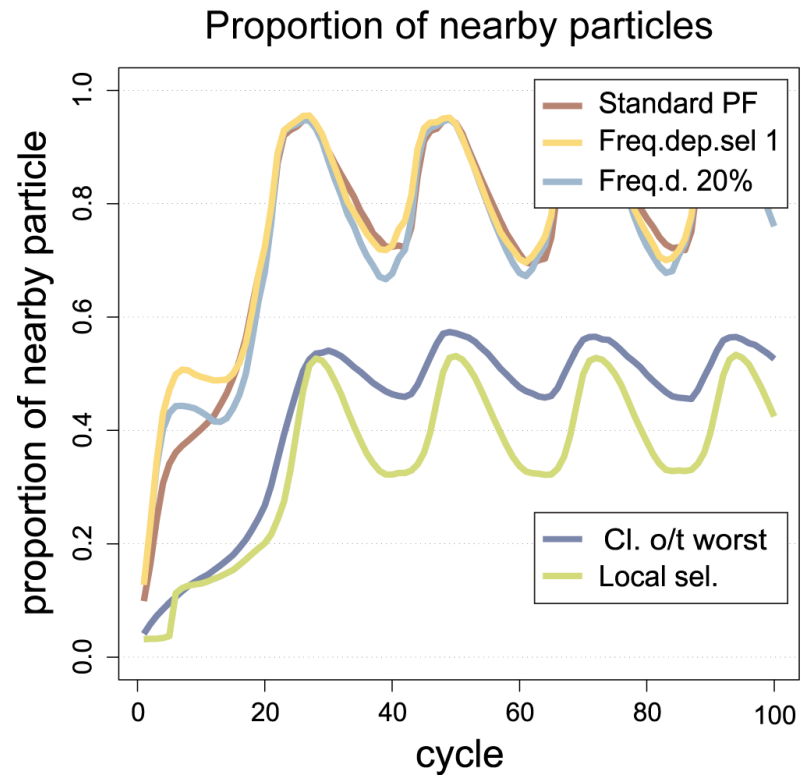

# Results: Diversity maintenance

---

- ▶ **Standard particle filter**
  - ▶ Poor diversity maintenance performance
- ▶ **Crowding (closest of the worst)**
  - ▶ Best performance
  - ▶  $O(\text{gg.cf.}N^2)$ , in our example faster than the standard
- ▶ **Frequency dependent selection**
  - ▶ Good performance
  - ▶  $O(\chi N^2)$ , little overhead
- ▶ **Local selection**
  - ▶ Good performance
  - ▶  $O(N)$ , but  $N$  varies somewhat

# Results: Compactness

# Results: Compactness

---

- ▶ **Standard particle filter**
  - ▶ Most compact
- ▶ **Crowding**
  - ▶ Not very compact and problem with loose particles
- ▶ **Frequency dependent selection**
  - ▶ Compactness similar to particle filter
- ▶ **Local selection**
  - ▶ Less compact

# Results: Estimation error

# Results: Estimation error

---

- ▶ **Standard particle filter**
  - ▶ Best estimation (NB not taking premature convergence into account)
- ▶ **Crowding / Closest o/t Worst**
  - ▶ Very good estimation in both environments
- ▶ **Frequency dependent selection**
  - ▶ Very good in ambiguous, but suffers from **ghost clusters** in non-ambiguous environments
- ▶ **Local selection**
  - ▶ Good estimation in both environments

# Conclusions and discussion

---

- ▶ Premature convergence is a problem in particle filters
  - ▶ For localization, as demonstrated
  - ▶ But also for particle filters used in SLAM (FastSLAM)
- ▶ Particle filters and genetic algorithms are very similar
- ▶ Niching methods can successfully be used in PFs
- ▶ Problems of loose particles and ghost cluster can be overcome

# Questions?

---

- ▶ Kootstra, G. & de Boer, B. (2009) Tackling the Premature Convergence Problem in Monte-Carlo Localization. *Robotics and Autonomous Systems* 57(11): 1107-1118.
  - ▶ [kootstra@kth.se](mailto:kootstra@kth.se)
- 

# Crowding

---

- ▶ for all particles  $i$ 
  - ▶ Apply motion and sensor model
- ▶ end
- ▶  $G_t \leftarrow \text{SAMPLE}(S_t, gg \cdot N)$
- ▶ for all particles  $i$  in  $G_t$ 
  - ▶  $\hat{S}_t \leftarrow \text{worst\_particles}(S_t, N/3)$
  - ▶  $C \leftarrow \text{uniform\_sample}(\hat{S}_t, cf \cdot N)$
  - ▶  $j \leftarrow \arg \min_{k \in C} (\text{dist}(i, k))$
  - ▶  $p_t^j \leftarrow p_t^i$
- ▶ end
